ABSTRACT

A non-aqueous electrolyte cell in which structural changes of the positive electrode active material are suppressed to increase the capacity further. The non-aqueous electrolyte cell includes a positive electrode containing a lithium-transition metal compound oxide as a positive electrode active material, a negative electrode containing a carbon compound or metal lithium as a negative electrode active material and a non-aqueous electrolyte interposed between said positive and negative electrodes. The lithium-transition metal compound oxide is represented by the general formula Li_xMnO₂ or Li_xMn_{1-y}Al_yO₂ where $0.94 \le x \le 0.96$ and $0.06 \le y \le 0.25$.
